ABSTRACT

The aim of the study was to correlate between tuberculosis and its predisposing factors and find out influence of Age, Sex, Occupation, Income, Dietary habits, Addiction (Smoking, Tobacco and Alcohol), Multiple drug therapy, Concomitant disease, Past history of Koch’s on the patients under the supervision of Dr. Mayank maheshwari (Physician, Maheshwari Hospital, Mathura). In the present study “Correlation study between Tuberculosis and its pre disposing factors” total 91 patients were included. In case of age, the subjects below 25 years were 18.68% between 25-50 years were 54.94% and above 50 years were 26.37%. In case of sex, 71.42% were males and 28.57% were females. While in case of occupation, 10.98% were students, 7.69% retired, 19.78% house wife and 61.53% employed. And in case of income, the subjects below 5000 Rs were 89.01%, between 5000-10000 Rs were 7.69% and above 10000 Rs were 1.09%. In case of dietary habit, 53.84% were vegetarians and 46.15% non vegetarians. In case of addiction, 14.28% were tobacco chewers, 4.39% alcoholics and 18.68% both (tobacco chewer and Alcoholics). In case of smoking habit 27.47% were smokers and 72.52% non smokers. In case of past history of Koch’s 29.97% were new cases and 78.97% relapses ceases.

Keywords: Tuberculosis, Vegetarians, Tobacco, Addiction.

INTRODUCTION

An increasing morbidity and mortality from tuberculosis (TB) in the near future is forecast for the world at large, with the number of newly occurring cases predicted to increase from 7.5 million a year in 1990 to 8.8, 10.2 and 11.9 million in the years 1995, 2002 and 2005 respectively; an increase amounting to 58.6 per cent over a 15-yr period8. The estimates were subsequently found to be appropriate for the year 2000 using a new method9. The proportion of tuberculosis cases co-infected with human immune deficiency virus (HIV) was also found to be rising, being 2-10 times greater for the 1997 estimates, than for 1992. The association with HIV and increasing multi drug resistant tuberculosis (MDRTB) appears to be a serious issue, especially for the developing nations. This infection is caused by one of two forms of mycobacterium Mycobacterium tuberculosis. Humans are the main host. The microbes cause pulmonary tuberculosis and are spread either by droplet infection from an individual with active tuberculosis, or in dust contaminated by infected sputum. Mycobacterium bow’s. Animals are the main host. The microbes are usually spread to humans by untreated milk from infected cows, causing infection of the alimentary tract. In Britain the incidence has been greatly reduced by the elimination of bovine tuberculosis and the pasteurization of milk. It is still a significant infection in many countries9.

PATHOPHYSIOLOGY OF TUBERCULOSIS

Once inhaled, the infectious droplets settle throughout the airways. The majority of the bacilli are trapped in the upper parts of the airways where the mucus-secreting goblet cells exist. The mucus produced catches foreign substances, and the cilia on the surface of the cells constantly beat the mucus and its entrapped particles upward for removal9. This system provides the body with an initial physical defense that prevents infection in most persons exposed to tuberculosis10. Bacteria in droplets that bypass the mucociliary system and reach the alveoli are quickly surrounded and engulfed by alveolar macrophage11, the most abundant immune effector cells present in alveolar spaces10. These macrophages, the next line of host defense, are part of the innate immune system and provide an opportunity for the body to destroy the invading mycobacteria and prevent infection15. Macrophages are readily available phagocytic cells that combat many pathogens without requiring previous exposure to the pathogens. Several mechanisms and macrophage receptors are involved in uptake of the mycobacteria15. The mycobacterial lipo arabinomannan is a key ligand for a macrophage receptor15. The complement system also plays a role in the phagocytosis of the bacteria15. The complement protein C3 binds to the cell wall and enhances recognition of the mycobacteria by macrophages. Opsonization by C3 is rapid, even in the air spaces of a host with no previous exposure to M tuberculosis5. The subsequent phagocytosis by macrophages initiates a cascade of events that results in either successful control of the infection, followed by latent tuberculosis, or progression to active disease, called primary progressive tuberculosis4. The outcome is essentially determined by the quality of the host defenses and the balance that occurs between host defenses and
the invading mycobacteria\textsuperscript{6,15}. After being ingested by macrophages, the mycobacteria continue to multiply slowly\textsuperscript{4}, with bacterial cell division occurring every 25 to 32 hours\textsuperscript{14}. Regardless of whether the infection becomes controlled or progresses, initial development involves production of proteolytic enzymes and cytokines by macrophages in an attempt to degrade the bacteria\textsuperscript{14,15}. Released cytokines attract T lymphocytes to the site, the cells that constitute cell-mediated immunity. Macrophages then present mycobacterial antigens on their surface to the T cells\textsuperscript{15}. This initial immune process continues for 2 to 12 weeks; the microorganisms continue to grow until they reach sufficient numbers to fully elicit the cell-mediated immune response, which can be detected by a skin test\textsuperscript{4,14,15}.

**AIM OF THE STUDY**

The aim of the study was to correlate between tuberculosis and its predisposing factors and find out influence of Age, Sex, Occupation, Income, Dietary habits, Addiction (Smoking, Tobacco and Alcohol), multiple drug therapy, Concomitant disease, Past history of koch’s on the patients.

**SUBJECT AND METHOD**

The study was carried out the medicine department hospital Mathura (U.P.). Total 91 patients satisfying the inclusion criteria of the study were enrolled. Potential study subjects were thoroughly interrogated for history in local dialect and questioned for detailed information pertaining to the disease. A through clinical examination – was done for both pulmonary and extra pulmonary tuberculosis by medical specialist. After provisional diagnosis, the subjects had to undergo following laboratory investigation for confirmation of diagnosis as inclusion criteria for study.

All subjects received standard antibiotic for a week during investigation phase of minimize the chance of diagnostic error before confirming for tuberculosis. The patients were followed upon a weekly basis during the period of treatment.

**Inclusion criteria**

- Patients of either sex
- Patients diagnosed with tuberculosis.
- Patients should be more then 12 years.
- Patients admitted to the ward or visiting medicine OPD of Maheshwari at least once a day.

**Exclusion criteria**

- Patients less than 12 years.
- Pregnant / lactating females.

**STUDY DESIGN**

This was an open, non comparative study to correlate between tuberculosis and predisposing factors in both outpatients and inpatients coming for treatment at Maheshwari Hospital Mathura (U.P.)

**STUDY SCHEDULE AND PLAN**

The patients were enrolled after oral informed consent as per the inclusion and exclusion criteria.

**ASSESSMENT**

- Age
- Dietary habit
- Sex
- Concomitant disease
- Income
- Occupation
- Addiction
- Past history of Koch’s
- Smoking

**RESULTS AND DISCUSSION**

<table>

In the present study we correlated the tuberculosis and it’s the predisposing factors in different categories of patients.

- With age group, the members of patients were found more between 25-50 years. This might be because of more interaction among this age group.
- With in sex group, the number of male patients was more than females. This might be because of frequent reporting of males.
- Within occupation and income group, tuberculosis was more prevalent in low income employed patients. This might be because of low income hence malnutrition status.
- Within dietary habit, tuberculosis was more prevalent in vegetarian than non vegetarian. Through the difference was not statistically significant as early reported.
• Within addiction, tuberculosis was more prevalent in both (alcoholics and tobacco chewer). This might be due to fibrogenesis and collagen tissue formation in the liver which disturbs the power of detoxication of liver and causes hepatic injury also acetaldehyde produced during metabolism appears to damage hepatocyte.

• Within smoking habit, tuberculosis was more prevalent in non smoker. This might be because of more smokers in society.

• Within past history of koch’s, there were relapses of tuberculosis. This might be because of irregular treatment or complete instruction behalf of treatment was not followed by the patients.
